DESCRIPTION:

The Antioch Dunes evening-primrose is a short-lived perennial plant in the evening-primrose family (Onagraceae). It forms large tufts with coarse drooping stems 4-40 inches long, much branched. Leaves are lance-like in outline, 1-5 inches long, 0.4-1.2 inches wide, with grayish hairs. White flowers open in early evening and close in the morning, and bloom from March to September. The petals are about one inch long and the stamens are yellow. The Antioch Dunes evening primrose may be confused with *Oenothera deltoides* ssp. *cognata*, which grows in the Oakley area southeast of the Antioch Dunes.

DISTRIBUTION:

Natural stands of the Antioch Dunes evening-primrose are found only on the riverine dune habitat located on and immediately adjacent to the [Antioch Dunes National Wildlife Refuge](#). The refuge is closed to the public except on docent-led tours.

The subspecies has been introduced to other locations but successfully persists only at the Antioch Dunes NWR and several other places: Tilden Regional Park in Alameda County, and

within some low riverine dunes at Brannan Island State Recreational Area just east of the refuge in Sacramento County.

THREATS:

At Antioch Dunes NWR, dust from the Georgia-Pacific gypsum plant adjacent to the Antioch Dunes NWR may be a threat to the listed species there. Georgia-Pacific allows access to their property for surveys, and the company has made attempts to reduce airborne gypsum dust beyond the standards for air pollution control. However, dust still enters the refuge.

Recreational use of the refuge and pedestrian traffic are no longer a significant threat due to the installation of a chain link fence. However, trespassers still illegally access the refuge and inadvertently trample rare plants.

A bigger threat is from inadvertently started wildfires. On several occasions a trespasser's campfire has started wildfires. Antioch Dunes evening primrose has life stages vulnerable to fire. This includes the period from germination during the beginning of the wet season in December through the deposition of seeds in mid-summer.

Invasive plants are one of the primary threats because they cause habitat loss. The most common invasive non-native grasses and forbs found at the refuge include rip gut brome (*Bromus diandrus*), winter vetch, (*Vicia villosa*) and star thistle (*Centaurea solstitialis*).

Low numbers of populations of any organism are also threatened by extinction through a single catastrophic event, such as an abnormally violent storm, a prolonged drought or other climatic event; or from an infectious disease; or from "stochastic" demographic fluctuations.
